Rotterdam Palatal Distractor

for surgically assisted rapid maxillary expansion
**Introduction**

Transverse maxillary deficiency in adolescents and adults is frequently seen in syndromatic as well as non-syndromatic patients including cleft patients. The transverse hypoplasia can be corrected by means of a surgically assisted rapid maxillary expansion. The treatment is an association of orthodontics and surgical procedures and provides dental arch space for lining up the teeth. The procedure also causes a substantial enlargement of the maxillary apical base and of the palatal vault, providing space for the tongue for correct swallowing and thus preventing relapse. In addition, a distinct subjective improvement in nasal breathing associated with enlargement of the nasal valve towards normal values is seen with an increase of nasal volume in all compartments.

Traditionally, the distractors for expansion are tooth-borne devices, i.e. hyrax appliances, which might have some serious disadvantages:

1. periodontal problems like buccal root resorption and cortical fenestration
2. segmental tipping and anchorage-tooth tipping
3. dental caries in syndromatic patients with poor oral hygiene

In contrast, with bone-borne distractors applied at a higher level in the palatal vault, most of the maxillary expansion is orthopaedic and at a more mechanically desired level.

In addition, the forces are directly applied to the bone and no tooth tipping and other unwelcome side effects are to be expected.
Indications

- Extreme transverse maxillary deficiency in syndromatic and non-syndromatic patients
- Anterior crowding and buccal corridors

Relative contraindications

- Class II deep bite; the distractor or the small activation rod on the palate may interfere with the teeth of the mandible. This can be overcome by placing the Rotterdam Palatal Distractor more distally or by wearing an occlusal splint during the distraction and consolidation period.

Absolute contraindications

- Extreme low palate; in case of an extreme low palate, the pins of the abutment plates will loose fixation and the distractor will not be stable.
- A general contraindication is an immune deficiency and irradiation.

Benefits

- Easily placed and activated
- No dental anchorage
- No screw fixation with possible damage to the (pre-)molar roots
- Easily blocked with a stainless steel wire
- Allows simultaneous orthodontic treatment with fixed appliances
- Easily removed with local anaesthesia

Special Notes

- For primary stabilization, the Rotterdam Palatal Distractor has to be slightly activated.
- One should realize that due to the mechanical principle of a car jack equal activation during the distraction period will result in a progressively decreasing distraction length. Therefore, in the course of the distraction, the rhythm of activation changes (see page 5).
- Patients with the Rotterdam Palatal Distractor have to keep up oral hygiene; regular visit to the oral hygienist is recommended.
**Intraoperative procedure**

**Rotterdam Palatal Distractor**

Intraoperative approach

Standard corticotomies of the anterior, lateral and median bony supports of the maxilla are performed. The palatal gingiva of the premolars is infiltrated with local anaesthesia including a vasoconstrictor.

Firstly, the Rotterdam Palatal Distractor is positioned temporarily with the abutment plates on the mucosa over the roots of the first or second premolars. The activation rod is in the midline and must not interfere with the lower teeth in occlusion. The distractor is slightly activated. Thus the print of the plates is clearly visible on the mucosa. Now the palatal mucosa on the anterior and occlusal side directly around the abutment plates is incised. The distractor is deactivated and removed.

The palatal mucosa slightly smaller than the abutment plate is removed. Local haemostasis is performed. The Rotterdam Palatal Distractor is placed again with the plates now on the bone. The distractor is slightly activated so the pins penetrate the bone stabilizing the distractor and, as a consequence, the vector.

**Note:**

Do not intend to place the distractor epimucosally (on the mucosa), as its sharp spikes might irritate the palatal mucosa and may cause pain and discomfort for the patient.

The number of turns is counted in order to know where to start in the distraction protocol. Finally, the distractor is secured with stainless steel wires around the premolars on both sides.

Distraction Diagram

showing the width of a 9 mm Rotterdam Palatal Distractor in relation to active distraction time

Distraction Protocol

Due to the mechanical principle (trigonometric function) of a car jack, equal activation will result in a progressively decreasing distraction length (see figure). Activation with 0.6 turn \((0.6 \times 360° = 216°)\) at the start of the distraction will result in a distraction length of 1 mm. After 5 mm of distraction, 1.3 turns \((1.3 \times 360° = 468°)\) are necessary to achieve the same distraction length of 1 mm. In the graphic, the changing length during the distraction period is demonstrated. As a result a distraction of exactly 1 mm per day is not feasible. To come close to the 1 mm and to achieve optimal patient’s comfort, different distraction rhythms have been selected:

1\(^{st}\) interval:
Closed distractor until 7 complete turns: 1 turn per day

2\(^{nd}\) interval:
From 7 turns (distractor is opened for approx. 7 mm) until 13 complete turns: 2 turns per day

3\(^{rd}\) interval:
From 13 turns (distractor is opened for approx. 14 mm) until 19 complete turns: 3 turns per day

4\(^{th}\) interval:
From 19 turns (distractor is opened for approx. 17 mm) until maximal distraction length: 4 turns per day

It is very important to note the opening length (amount of turns) of the distractor during the placement in order to know where to start in the scheme respectively in which interval.

- Latency period: 7 days
- Distraction is performed according to the different intervals by using the patient screwdriver (item no. 51-555-95-07).
- Consolidation period after distraction: 3 months
- Orthodontic treatment can already be started or continued during the consolidation period
Clinical examples

Case 1 – Non-syndromatic patient
Non-syndromatic patient with mandibular retrognathia and transverse maxillary hypoplasia

Case 2 – Non-syndromatic patient
Non-syndromatic patient with mandibular prognathia, open bite and narrow-tapered arch form

Case 3 – Non-syndromatic patient
Non-syndromatic patient with mandibular retrognathia and transverse maxillary hypoplasia

Case 4 – Syndromatic patient
Syndromatic patient with Treacher Collins including transverse maxillary hypoplasia

Removal of the distractor
At the end of the consolidation period, the distractor can be removed in an out-patient clinic. The palatal mucosa surrounding the distractor is infiltrated with local anaesthesia including a vasoconstrictor. The stainless steel wires are removed, the distractor is deactivated and removed (picture 1). The healing of the mucosa is normally complete within a week (picture 2).
Design of the Distractor

The Rotterdam Palatal Distractor is a bone-borne distractor which can easily be placed and activated. It has the design of a car jack and is totally made of titanium grade II. By activating the distractor, the 2 mm long pins of the two abutment plates will penetrate the bone and the device is stabilized automatically. No screws are necessary to fixate the distractor to the bone. At the end of the distraction period, the distractor is easily blocked with a stainless steel wire.
